Fall 2019, Graphic Elective
Critic Phillip Crupi, Joseph Brennan

Instead of being passive consumers of trendy ideas or knowledge. Architecture can perform based on cultivating alternative ways of being in the world as guardian of its context. I see potential for an architecture that could reflect, criticize and propose an exit from the prevailing spatial models. In this portfolio, each project is an alternative existence to its 'hype' counterpart.

01. THE WRAPPING LAYER

A hypothetical art museum wrapping the front of house with back of house, treating both as gallery space. A museum with only galleries.

Precedent Study Drawing
 ^ Whitney Museum
 v Sir John Soane's Museum

Gallery as big as a block - Whitney Museum of American Art

Gallery as small as a recess - Sir John Soane's Museum

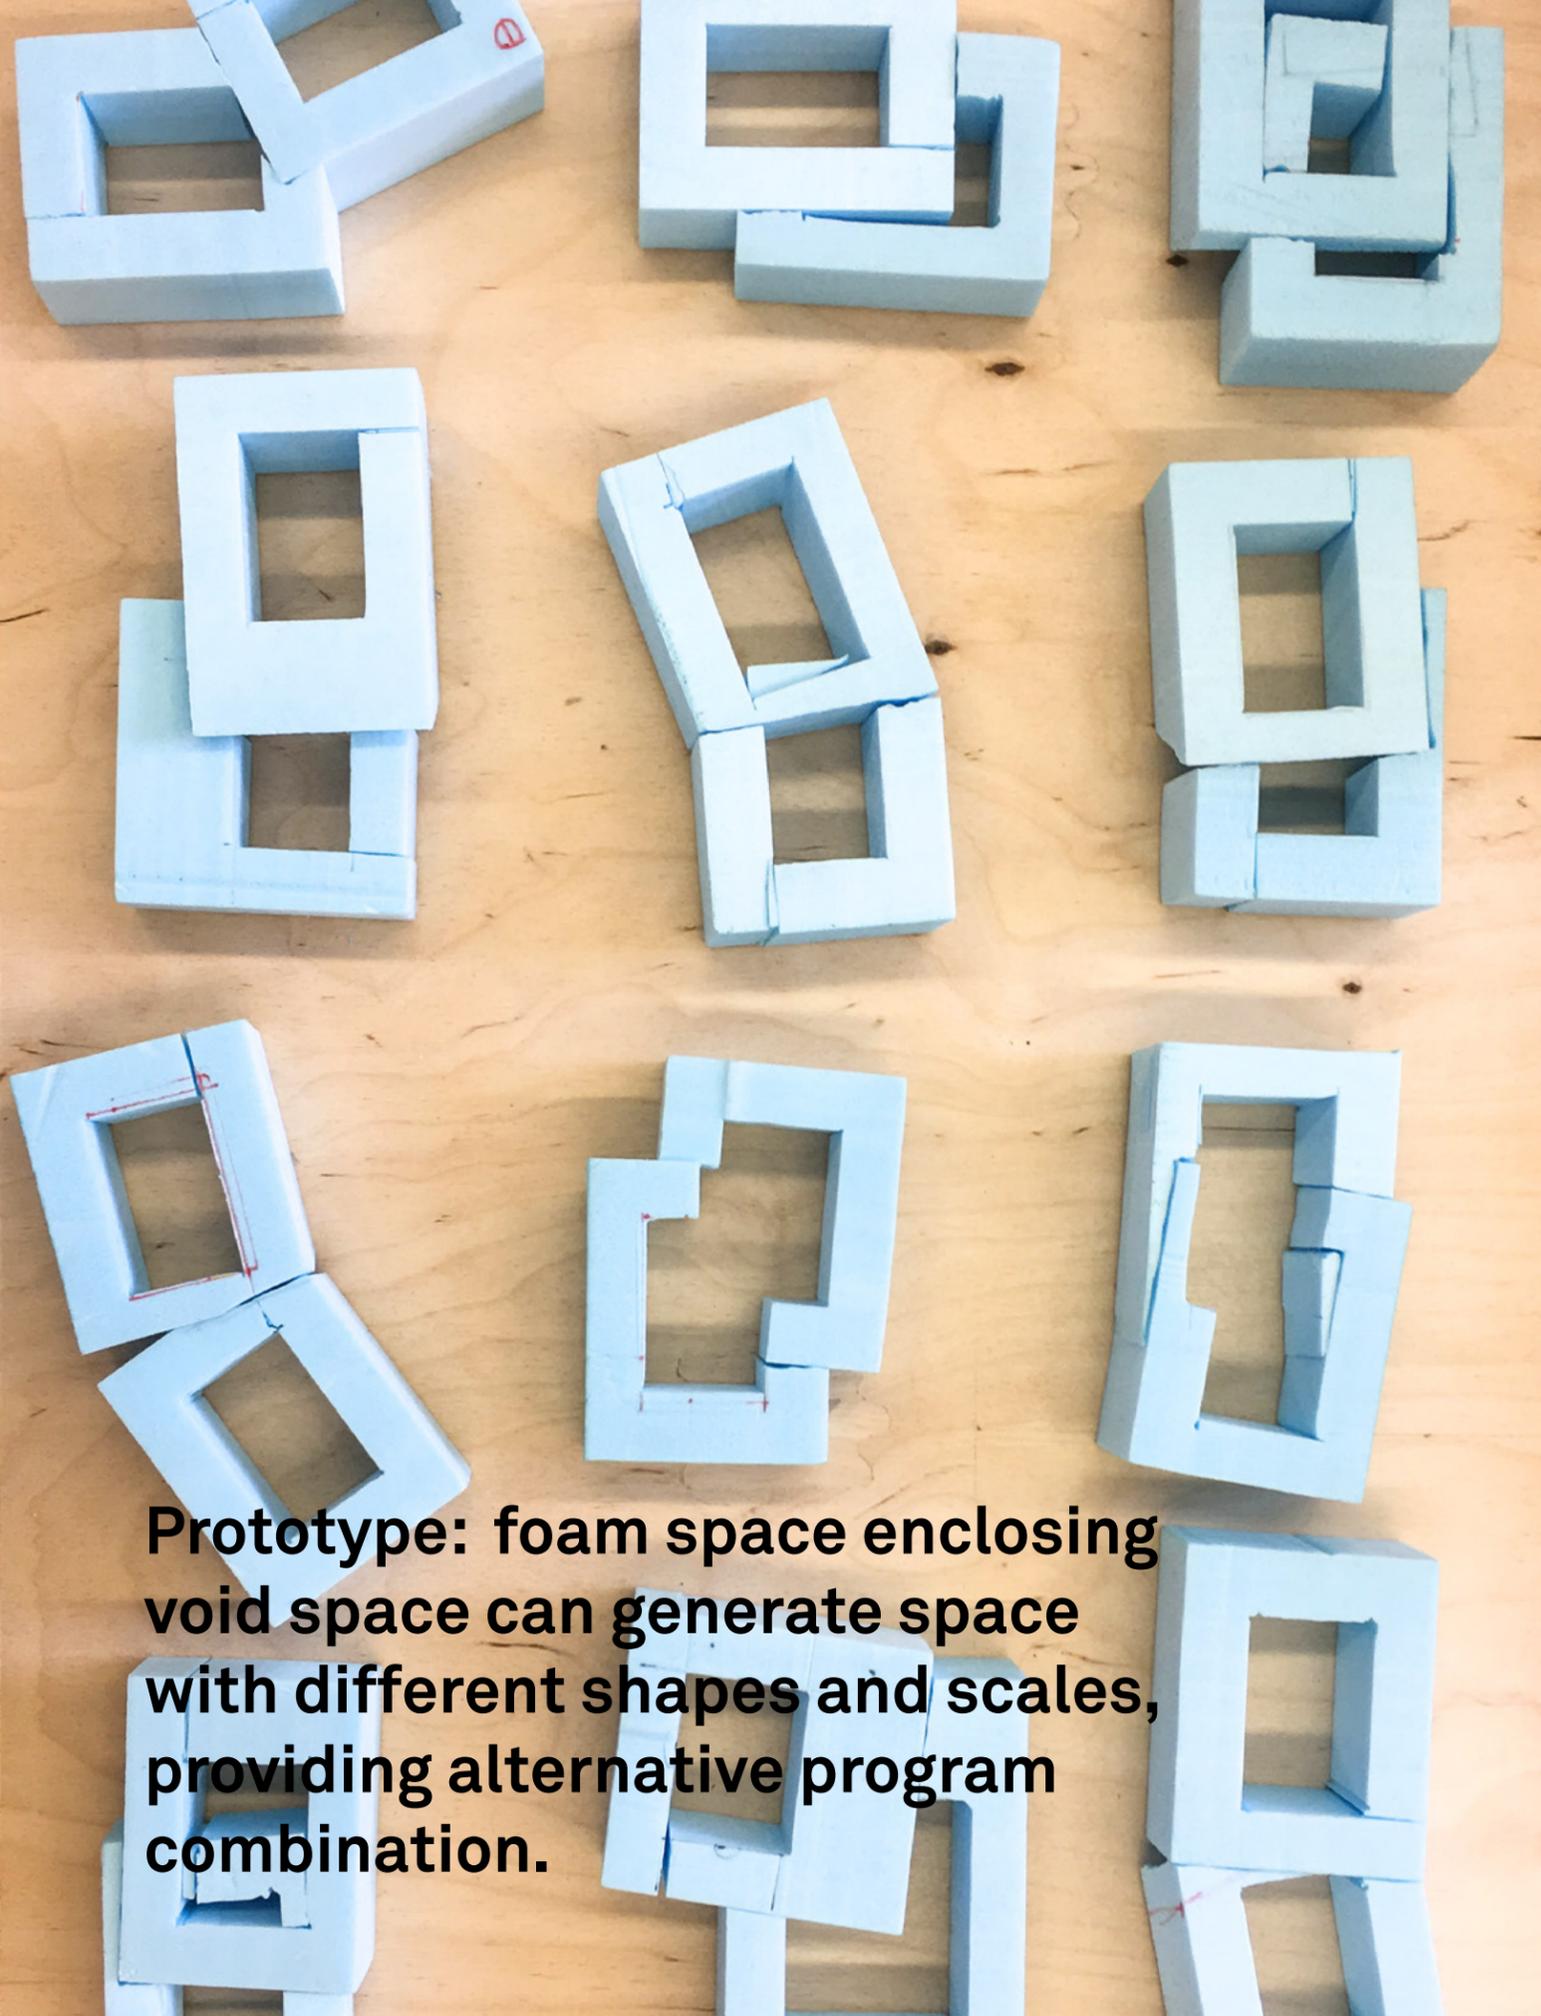

In the world of museums, as more portions of non-gallery space are becoming galleries, we envision a museum with only galleries, an architectural device that downplay such binary program distinction, an alternative type of museum.

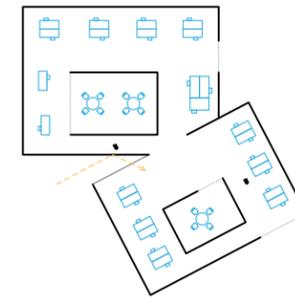

From two precedents, the poché with diverse scales in Sir John Soane's Museum and the transparency of workspace in the Whitney Museum suggest more and more flexibility of galleries / museums. Therefore, We proposed a prototype with the back of house wrapping the front of house. By paring such units, we can create

rooms with different scales and connections between the two type of space.

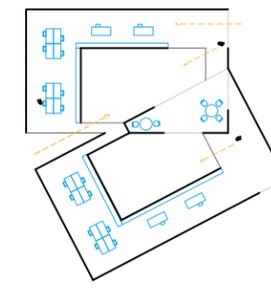

As a response to the brief - museum with only galleries, we designed a hypothetical art museum composed of units hosting both art and its armature, space with a wide range of scales to flexibly exhibiting the back of house as part of the exhibition, providing an alternative experience for artists, museum goers and curators.

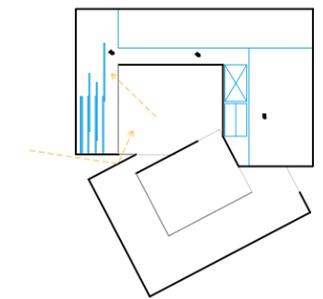

Prototype: foam space enclosing void space can generate space with different shapes and scales, providing alternative program combination.

1st floor plan

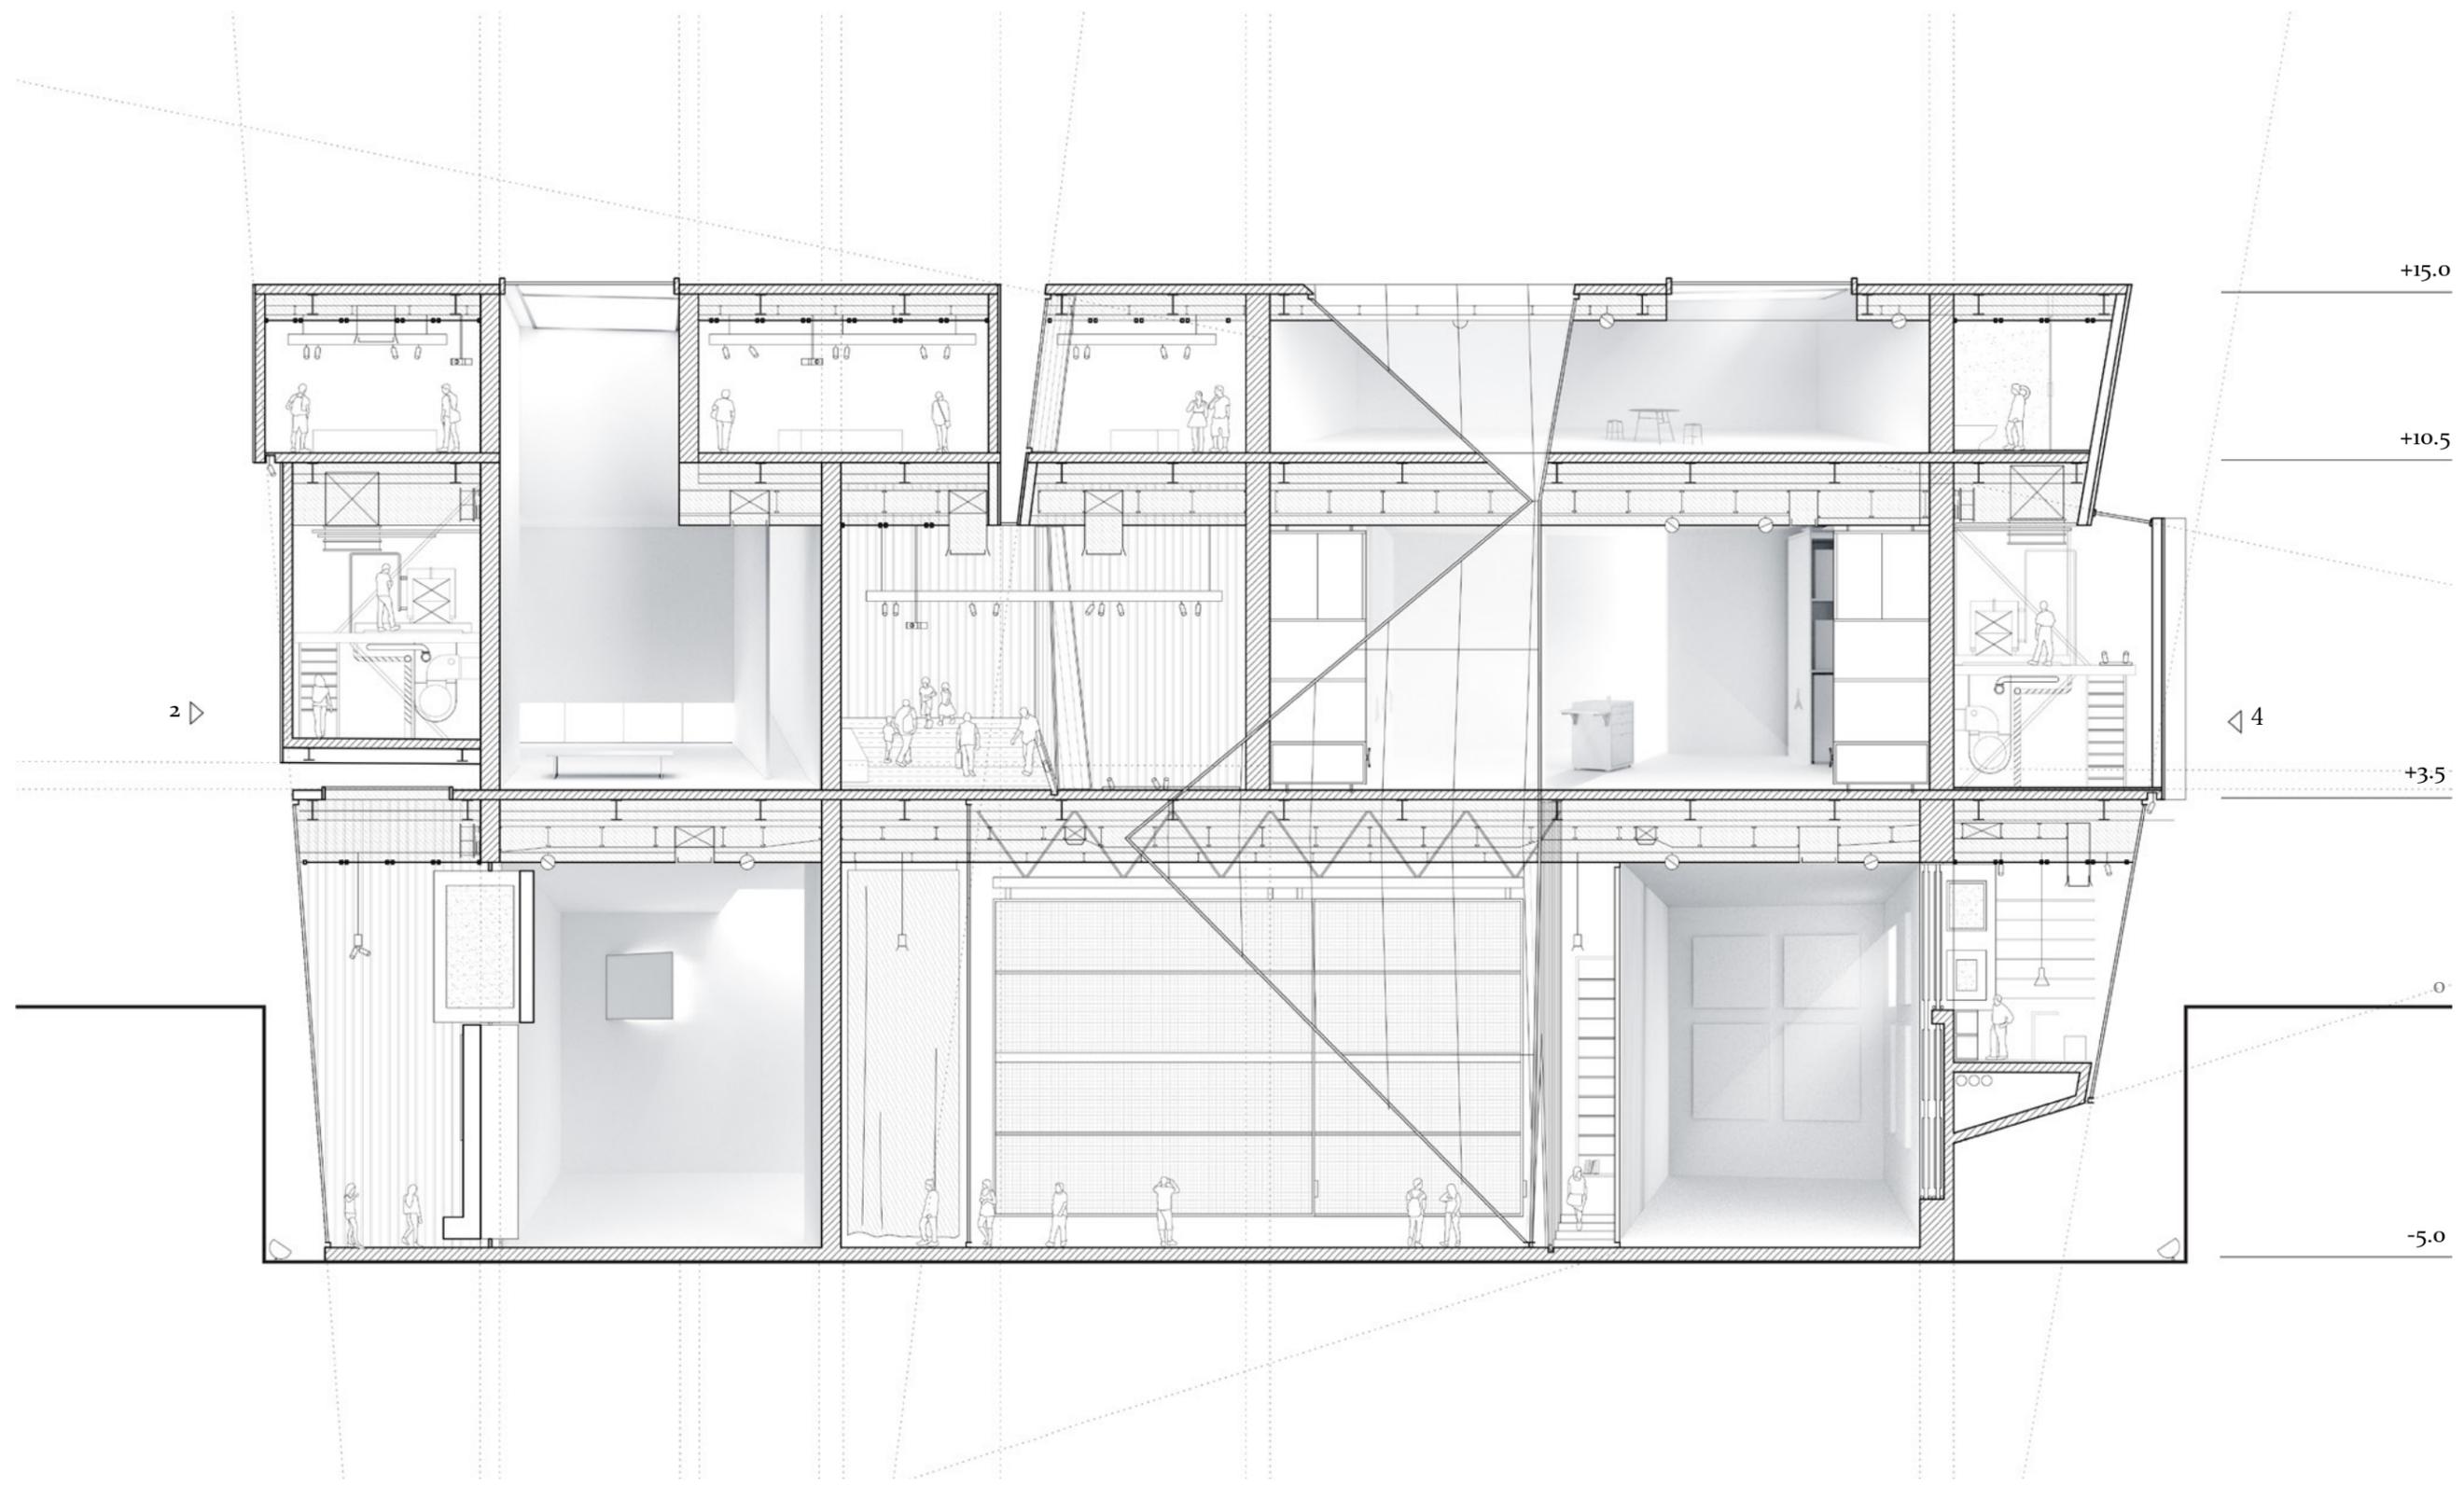

The wrapping layer acts as the armature for art. The spatial quality of the wrapping layer is complex, contextual, and raw, which is on the contrary to the neatness of the wrapped layer. Art exists not only in a de-contextualized white box, but in a contextual world of how it is processed, preserved and stored.

The operation of paring introduces a third spatial type – the crack. The crack brings light to the wrapped layer in a moderated way, both on plan and on section. The crack brings a sense of position to human bodies, It also creates a gallery type that is interactive with the city: visitor positioning themselves in the city and pedestrians spectating the museum from the street.

02. MINNING THE CITY

A non-extractive strategy to relocate New York's material excess to radically decarbonize its environmental impact and improve building envelope performance.

What if the materials we need is already in our city?

Under the Paris Agreement, a series of documents in different fields and scales are set in place in order to mitigate global warming. Among those documents. We look closely to the building sector as the start of our discourse. The Green New Deal resolves to upgrade all existing buildings to achieve maximum energy efficiency, which corresponds with Bill de Blasio's 80x50 plan. A plan by the New York City Mayor's Office of Sustainability. In New York City, Around 14,000 buildings need to improve energy performance in order to achieve the 2050 target. 17% of that improvement comes from envelope upgrade.

Upgrading with traditional construction method contains massive embodied energy which comes from mining, transportation, bulk manufacturing, storage and constructing. In the meantime, replaced materials would go through

transfer stations, multiple waste processing facilities, and more than half of them ends up in landfills. According to research, embodied energy would rise from 32% to 67% if we upgrade our building with conventional mode. Even Buildings using recycled materials has an 80-year carbon debt to be paid

So instead of mining the nature, what if the materials we need is already in our city? There is an abundance of materials that could be stripped to update our buildings in New York City. Decorative steel of skyscrapers in the 60s, stone panels on post modern buildings, partition walls in post-war commercial buildings and glass on glass towers could all be stripped as building materials.

A just-in time system for the city

To treat our city as a production system, different building types provide different material supplies, and at the same time require materials to retrofit. The supply and the need exist right next to each other or even overlaps in some buildings. Therefore, we can create a **just-in time** material mobilization system that transforms excessive and inefficient materials from existing buildings to high-performance sustainable materials in real time. The material exchange and upgrade could happen within the city instead of the whole globe, reducing

its carbon footprint. Multiple retrofit projects would happen simultaneously. Materials would be dismantled, transported, fabricated and remounted as a common scene in our future city.

In a moment like this when so many people make efforts intervening on reconfiguring building environment. We try to invent the next exchange platform of material transformation due to the necessary replacement of materials for reducing carbon emissions.

Materials would be dismantled, transported, fabricated and remounted as a common scene in our future city. A new aesthetic is introduced to our city with existing building languages.

and transparency.

To upgrade the city. It's not about making one nice building with cutting edge technology. It's about the whole process and its embodied energy, which comes from mining, transportation, bulk manufacturing, storage and constructing. In the meantime, dismantled materials would go through transfer stations, multiple waste processing facilities, and some of them end up in landfills.

All of the above contributes to the embodied energy of building materials. According to a research, embodied energy would rise from 32% to 67% if we upgrade our building in conventional mode by 2050. Even Buildings using recycled materials have a 80 year carbon debt to be paid. But we don't have that much time left. The conventional mode keeps requests material from nature to buildings, causing the shrinkage of up to 90% of the beaches.

In 2100, the only place you can find a beach might be in a history book. So instead of mining the nature, what if the materials we need is already in our city?

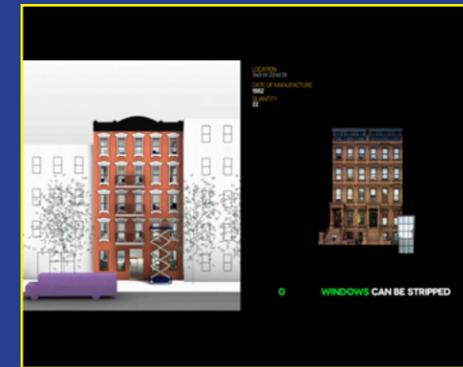

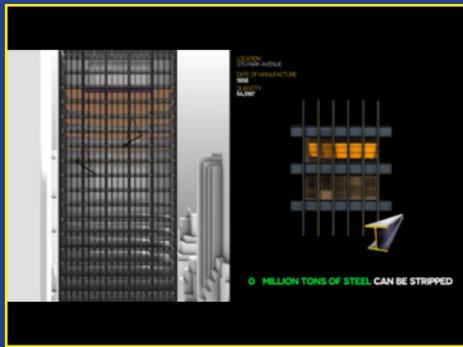

As you can imagined. Materials in our city would be mitigated through such new materiality. A materiality based on mobility and energy efficiency.

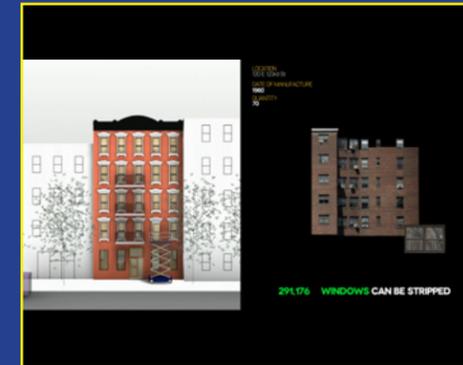

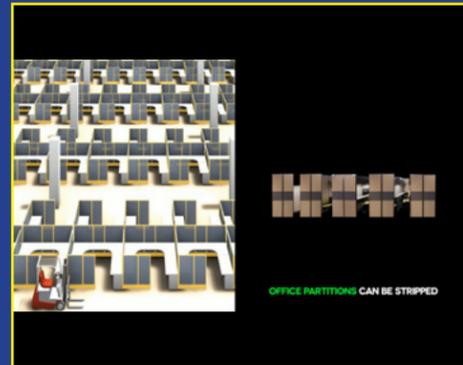

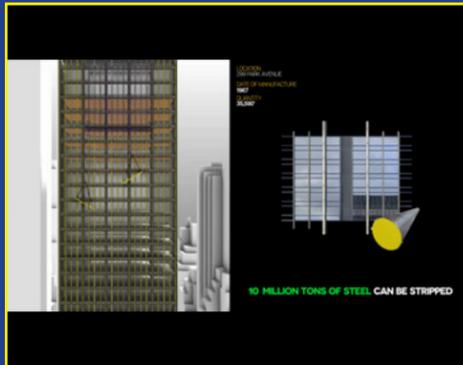

Avenues, train rails and ferry lines would be mobilized for material transportation.

Certain empty slots, vacant buildings would be appropriated temporarily for material fabrication.

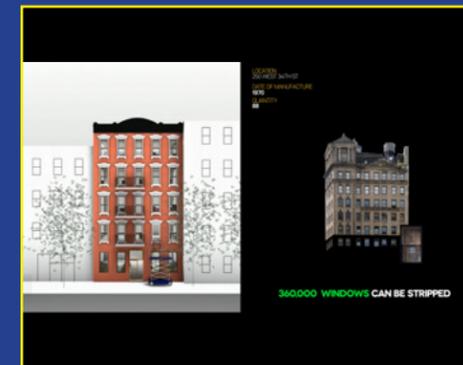

As materials are being transformed from one building to other buildings, scaffold system, protection (from noise and toxicity) system, deconstruction system, settlement system would be implemented for the security of tenants, citizens and workers.

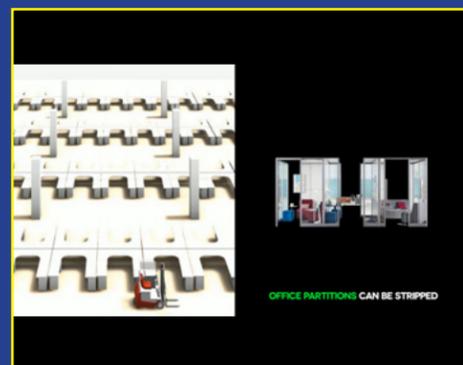

When we look into New York City, there is an abundance of materials that could be available to upgrade our buildings.

To treat our city as a production system. Different buildings provide different material supplies. at the same time. They require materials to retrofit. The supply and the need exist right next to each other or even overlaps in some buildings. The upgrade doesn't need to cover the carbon footprint of the whole globe. Instead, it could happen within 2 miles.

Therefore we can create a market for reused materials. Eventually the cost of carbon fines will come down to the tenants. A market as such will act as an incentive for building upgrade.

Buildings in the 60s use steel as decorative facade elements. They are beautiful as decorations but they can also be excessive when there are too many of them. These steel can be stripped down and reconfigured into other elements while the facade remains intact with much less materials;

Neo-classical buildings use massive amount of stones for aesthetic purposes. However, with the problem we are facing, these materials can be seen excessive. We can strip down some of the stone materials for other purposes while providing these building with better lighting.

Partition walls in post and pre-war commercial buildings were really popular and they are still in use today. These materials can be stripped down while we introduce a more open working environment;

The modern glass towers contains massive amount of glass. Do we really need that much of glass for our towers? Why don't we replace some of the glass with solid panels so that we can improve the window-to-wall ratio while maintaining the needed light for interior. Those replaced glass can then be reconfigured as raw materials.

According to 80*50, all NYC's single pane window need to be replaced to meet the requirement. And that means a massive amount of windows will be stripped down. And through digital fabrication, special treatment, These glass have the potential to be used elsewhere.

The technological approach is still driving us apart from the reality that we live in. The scale of climate change is so large that no one can fully comprehend.

The gap is so huge between climate change as a symbol and climate change as a reality.

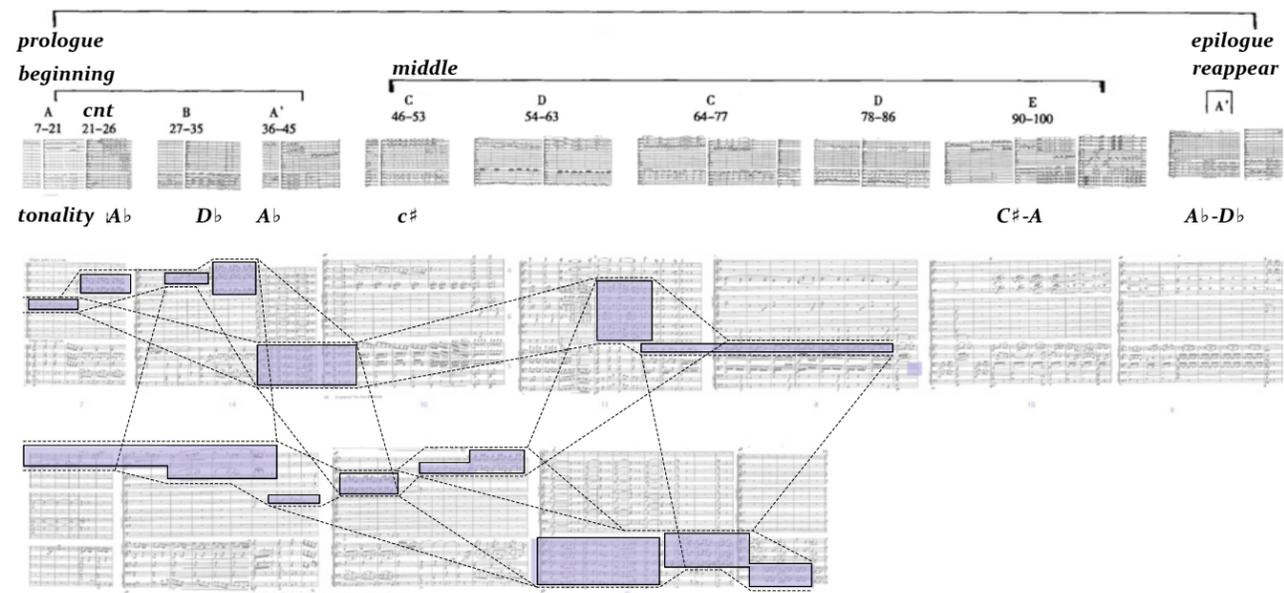

We designers can make the gap smaller by bringing the idea closer to people. Changing people's aesthetic from the addiction to cleanness to awareness for climate issues. If mining the city is a common scene in our life and the idea become something we can see and touch. Then I think we are one step closer to tackle the crisis.

03 . R E C U R R I N G M E L O D Y

**Based on a piece of music,
an exploration for alternative
language, materiality and
urban presence for concert hall.**

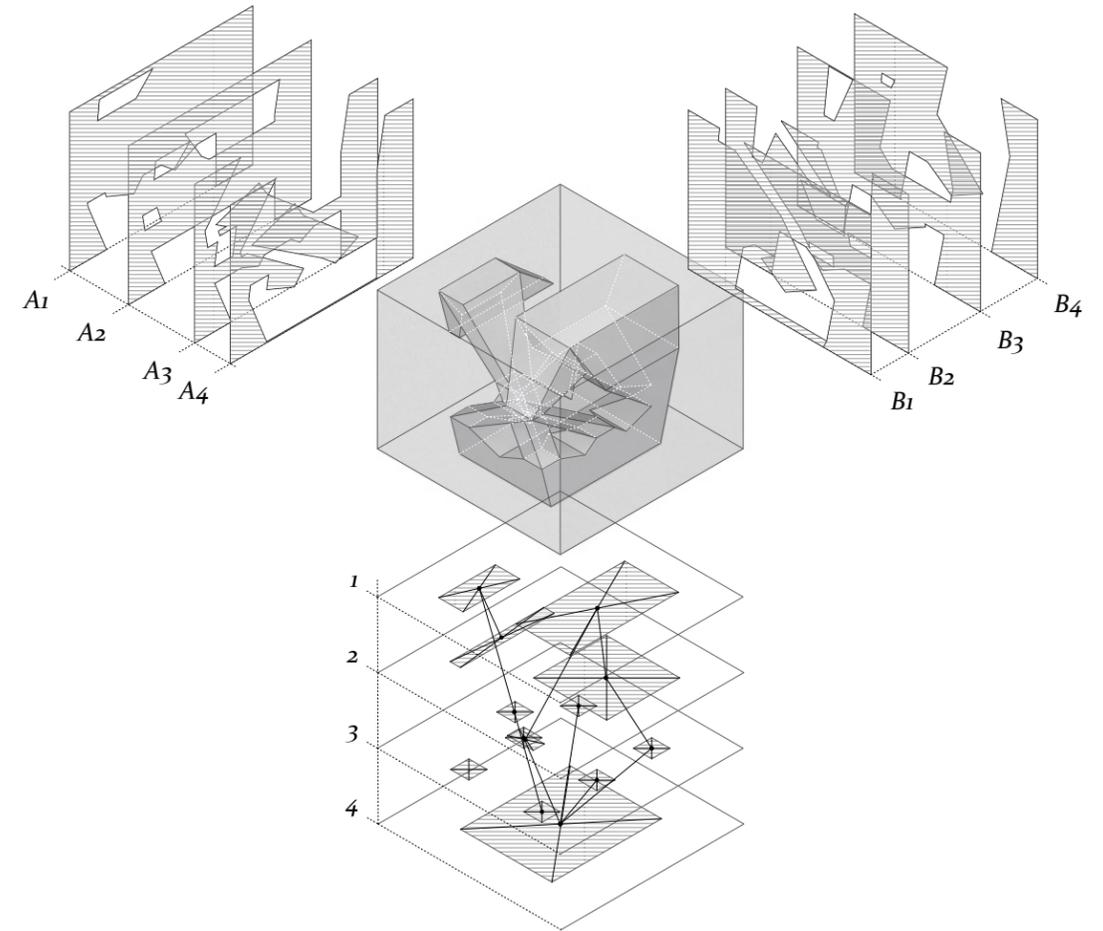

In the New World Symphony by Antonín Dvořák, a theme melody reappears in a classical Sonata format. The melody was based on black soul music, which constructs the overall nostalgic expression for the chapter. The melody was composed in different instrumentations and configurations throughout the whole score.

It is an irregular space carved from a classical framework. One melody is expressed with multiple fashions. In architectural language, what would a

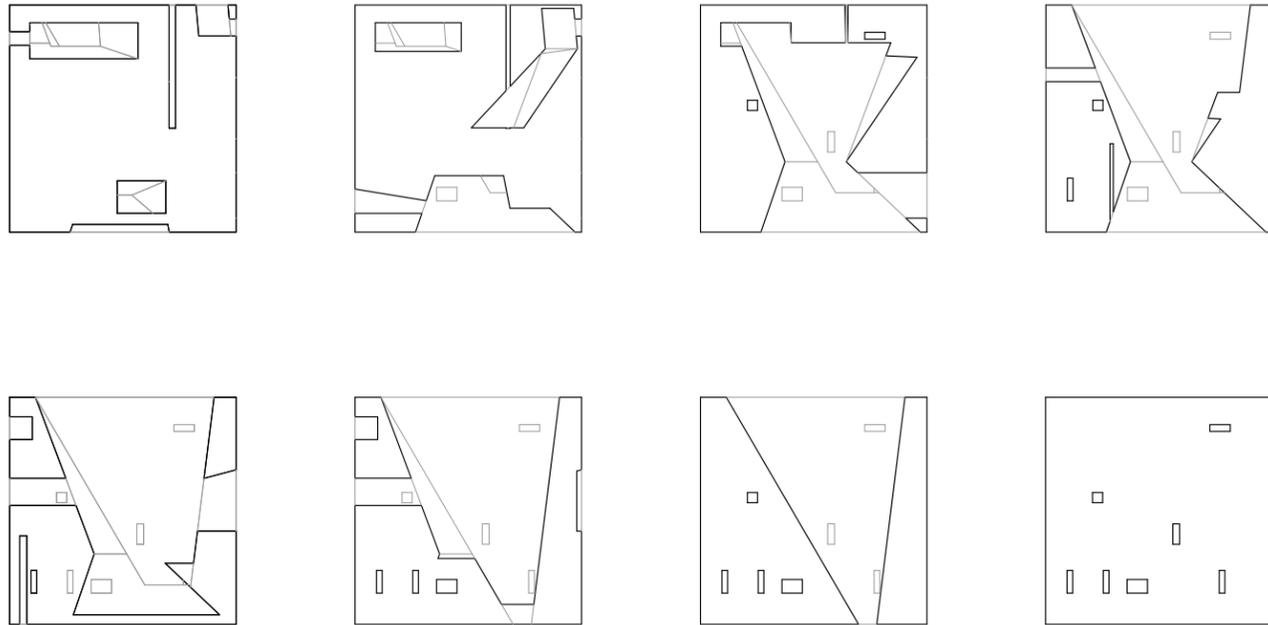

space with recurring melody be like?

When extruding rectangle patterns vertically and boolean extracting it from a cube, there is an irregular void in a nondescript volume. Through section from x and y axis. A series of new patterns are generated, showing the duality of irregularity and classical framework.

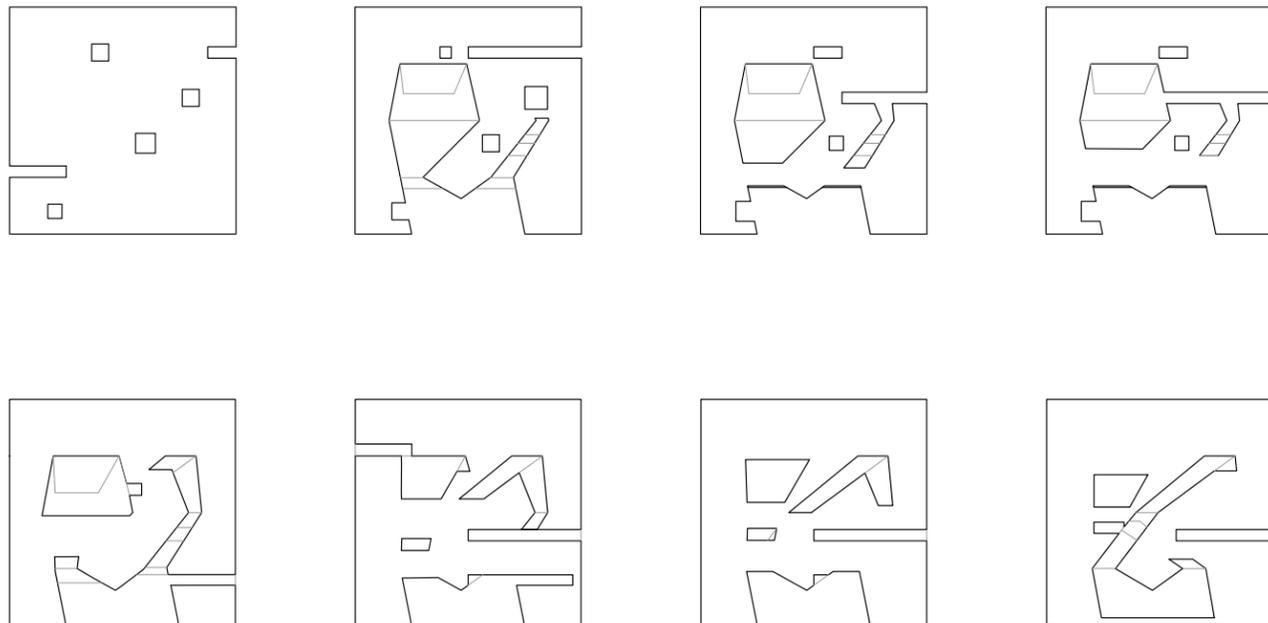

^ Spatial prototype of recurring melody
< Classical structure and theme melody

(a)

(b)

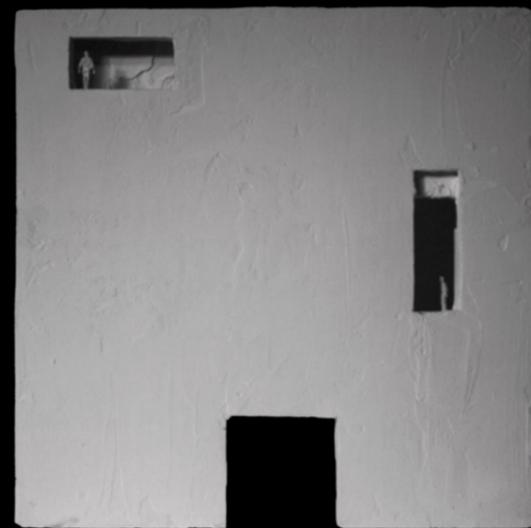

The section series change when operating the extrusion differently. Through the series, shapes interact with each other in a nuanced way: separating, connecting, growing, diminishing, evolving. Each section is unique in its configuration and expression, yet there is a continuum when seen as part of the series.

From digital to physical model, layers of each section are made into thick materials, the smoothness of the volume transforms into a different materialized language: crude, opaque, terraced. From music to architecture, the recurring melody becomes a way of form-finding. The results are thick 'acoustic' blocks with vastly different expressions.

< Section series
 > ^ Study model of result (a)
 > v Study model of result (b)

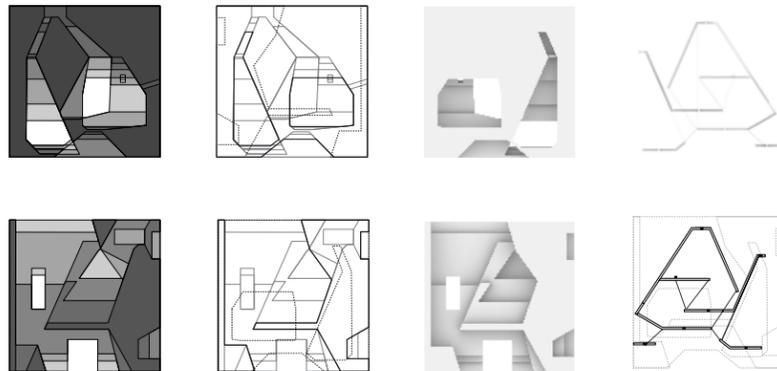

**The blocks are thick walls
with a public appearance.
A kind of frontality with
language from music.**

The In-between Space

< Isometric model view
> The in-between space

Blocks are independent elements translated from music into architecture. A piece of music is never fragmented. What would be the connecting elements when placing different blocks together?

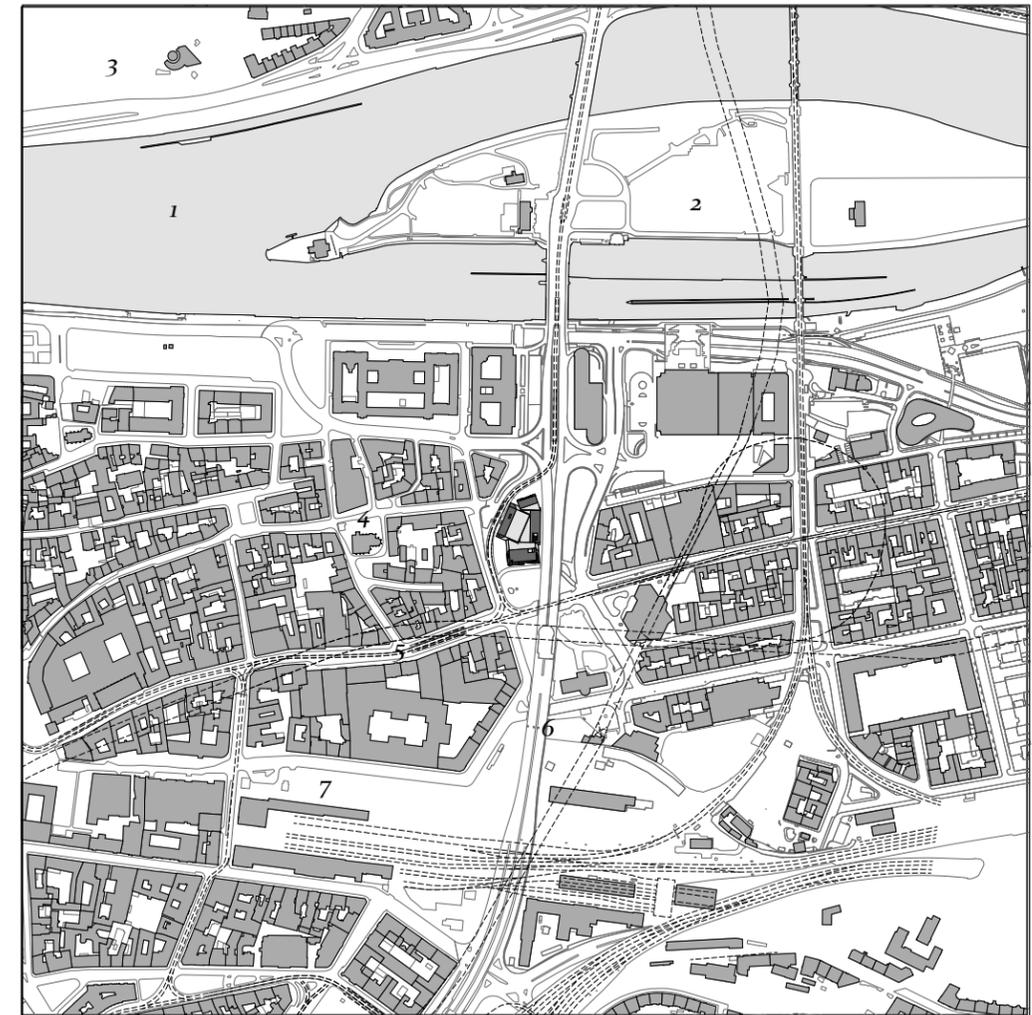

Analysis diagram
1. porosity
2. shape
3. frontality
4. in-between elements

Through analysing, blocks differ in terms of porosity and spatial quality based on their section shapes. Juxtaposing two together, linear and planar elements are extracted from the shapes and connect the two blocks, creating an in-between space. Solid, planes and lines construct the whole space, the shape of each elements are interconnected. Together, blocks and the in-between space become the language for this project.

The site plan attempts to show that the four blocks enclose the site in a typical European courtyard context. Yet, from an aerial view, the building stood out with its original language.

- 1. Vltava, longest river in Czech Republic
- 2. Štvanice, island between Holešovice and Karlín
- 3. Letná Park, overlooking the Prague Old Town
- 4. Petrska, historical street
- 5. Na Poříčí, historical street
- 6. Wilsonoma, overpass
- 7. Praha Masarykovo Nádraží, terminal railway station

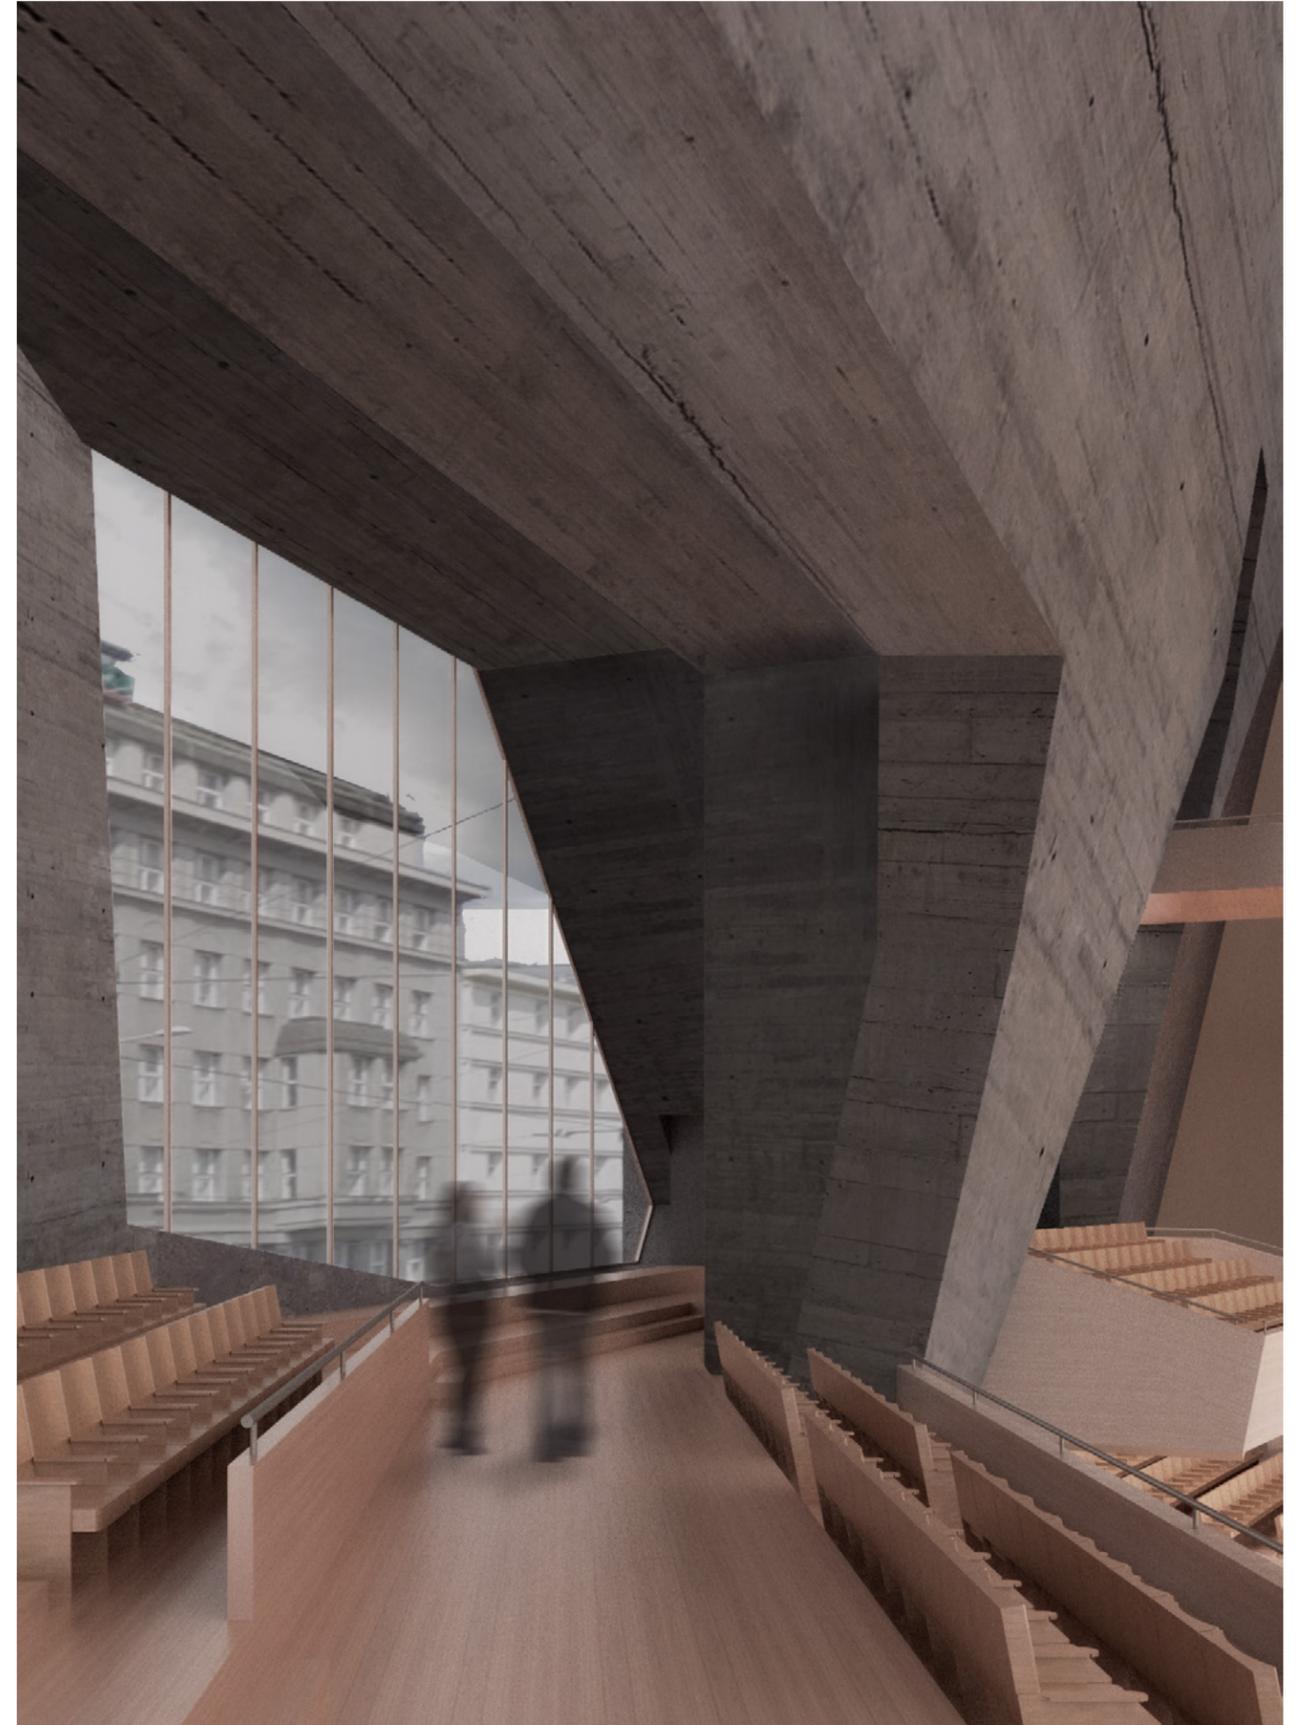

^ Study model with scale figure
< View from historical street Petrska

The language of the block has a public appearance in an urban scale. The voids suggest space of public gathering. The frontality of the building stems from the nature of music.

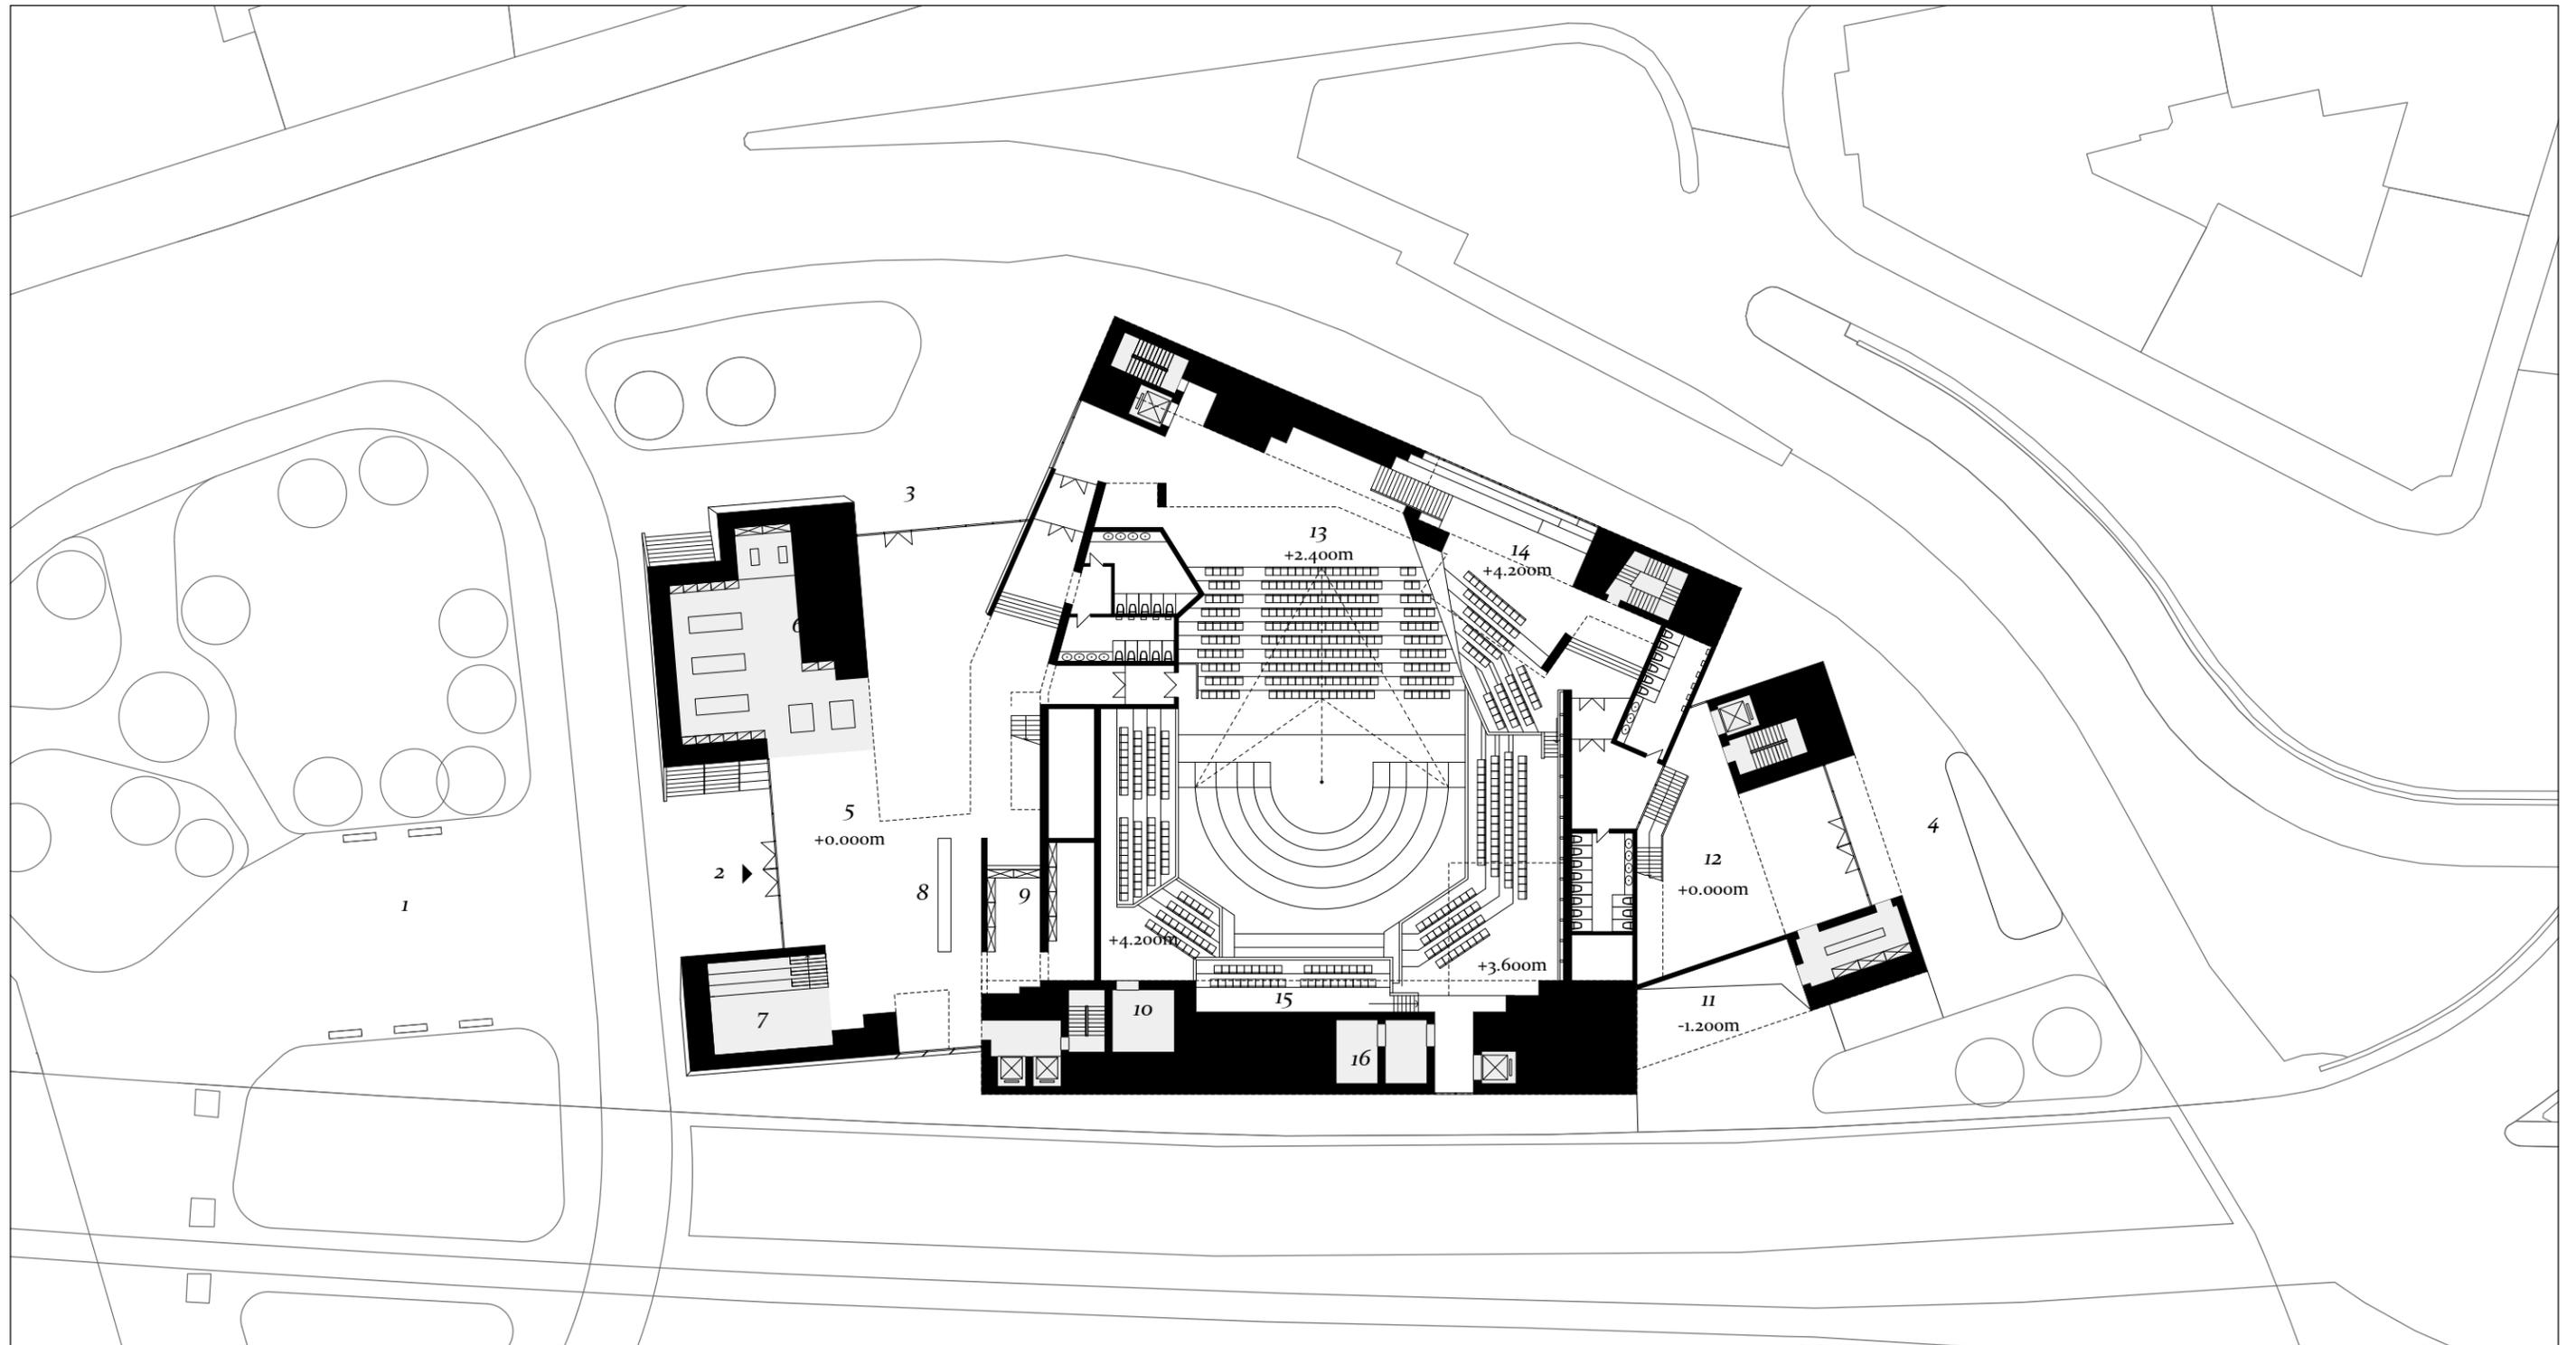

^ Study model with scale figure
> Interior view inside the void

The voids also have a public appearance from interior of the building. A space connecting the auditorium to the city.

INTERIM URBANISM

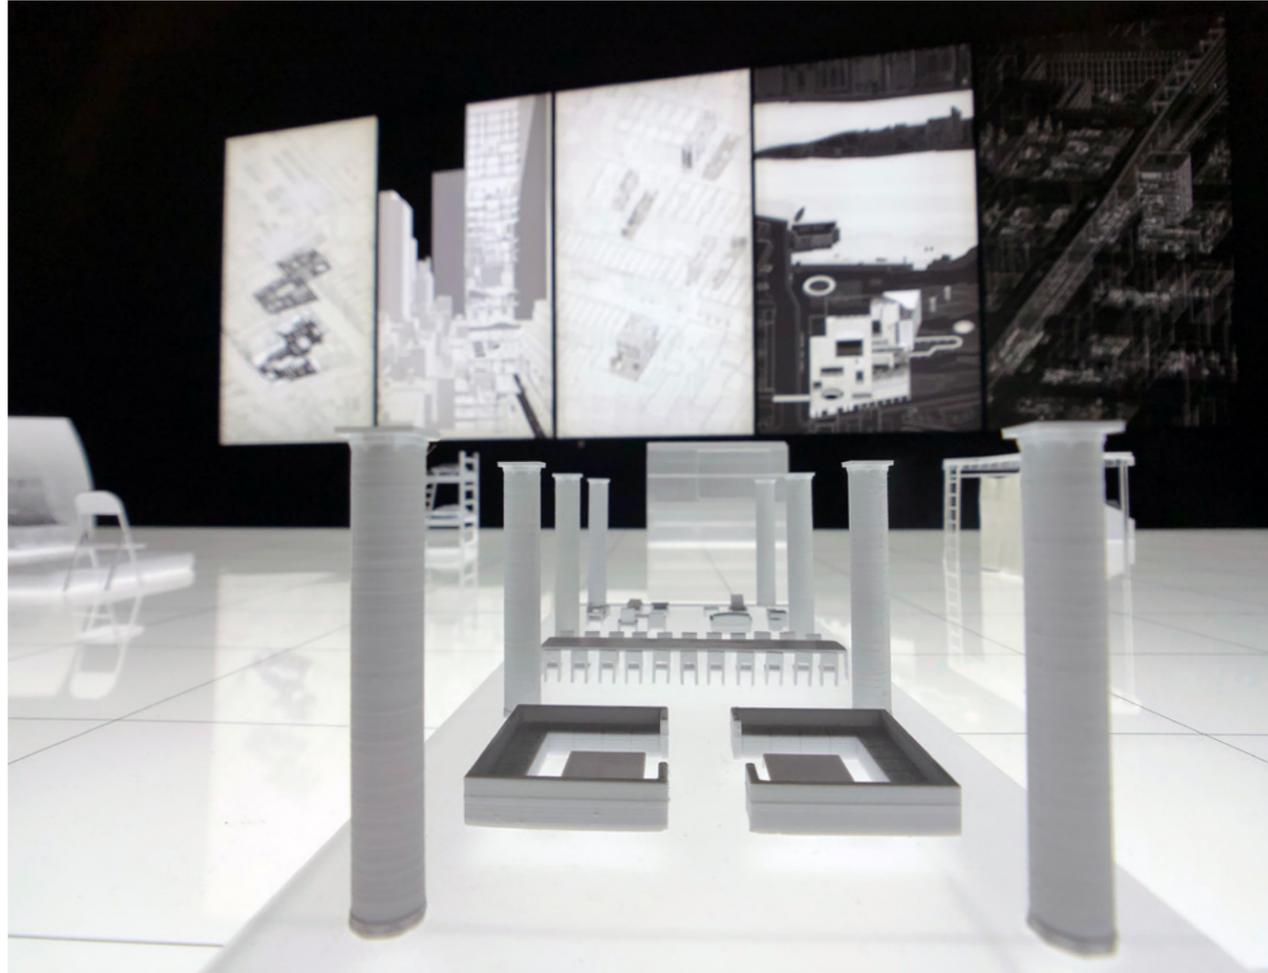

**The materials assembled for
the 2019 Seoul Biennale of
Architecture and Urbanism
“Collective City”**

The materials assembled for the 2019 Seoul Biennale of Architecture and Urbanism “Collective City” present selected critical instances and projections set forth around the historical and contemporary conditions of youth dwelling in New York City, U.S.A.

I mainly worked on one of the proposals - **HQY**, both drawing and design. Reconfiguring a 560,000 sqft Department of Education warehouse building in Queens where Amazon planned its now-canceled headquarter HQ2, **HQY** is a new youth complex that combines a large number of youth housing and work units with a new public higher education institution. Envisioned as an open campus alternative to highly privatized educational enclaves, the waterfront facility combined with the adjacent wetland integrates the legacy of art and industry of the area as well as new environmental and educational initiatives.
